99mTc-tetrofosmin, Thallium-201-chloride ($^{201}$Tl) and 99mTc-MIBI imagings were performed in a patient with malignant thymoma. Tracer uptake in the primary tumor was demonstrated. The tumor-to-background ratios of planar and SPECT imagings were 1.60 and 1.98 for $^{99m}$Tc-tetrofosmin, 1.12 and 2.09 for $^{201}$Tl, and 1.19 and 1.80 for $^{99m}$Tc-MIBI, respectively. In another patient $^{99m}$Tc-tetrofosmin and $^{201}$Tl imagings were performed. Not only the primary tumor but also the direct invasions and metastatic lesions (bone metastases) were clearly detected. The tumor-to-background ratios of planar and SPECT imagings were 2.31 and 2.78 for $^{99m}$Tc-tetrofosmin and 2.45 and 3.58 for $^{201}$Tl, respectively. In $^{99m}$Tc-tetrofosmin scintigraphy we acquired delayed images, and the tumor-to-background ratios of planar and SPECT delayed images were 1.20 and 1.86, the retention ratios were −1.11 and −0.92 and the retention indices were −48.1 and −33.1, respectively. Our preliminary results suggest that $^{99m}$Tc-tetrofosmin is useful in detecting not only the primary tumor but also metastatic lesions from malignant thymoma.

Key words: thymoma, $^{99m}$Tc-tetrofosmin, $^{201}$Tl, $^{99m}$Tc-MIBI, SPECT

INTRODUCTION

$^{99m}$Tc-1,2-bis(bis(2-ethoxyethyl)phosphino)-ethane (tetrofosmin), a lipophilic monovalent cation, has recently been introduced as a new technetium-labeled pharmaceutical for myocardial perfusion studies. $^{99m}$Tc-tetrofosmin and $^{99m}$Tc-MIBI are now widely used in myocardial perfusion imaging. $^{201}$Tl, a cationic material, is a useful tracer for detecting various tumors including thymoma. $^{99m}$Tc-tetrofosmin as well as $^{99m}$Tc-MIBI have shown potential utility as a tumor imaging agent for parathyroid adenoma, breast cancer, lung cancer, thyroid cancer and other tumors. We report patients with malignant (invasive) thymoma who underwent $^{201}$Tl, $^{99m}$Tc-MIBI and $^{99m}$Tc-tetrofosmin imagings.

CASE REPORTS

Case 1
A sixty-seven-year-old man entered our hospital complaining of double vision and right eyelid ptosis. A tension test was positive and a clinical diagnosis of myasthenia gravis was made. Thoracic CT revealed an anterior mediastinal tumor (Fig. 1). The result of CT guided biopsy was a malignant thymoma. We obtained informed consent from the patient. $^{99m}$Tc-tetrofosmin and $^{201}$Tl imagings were performed. The patient was injected with $^{99m}$Tc-tetrofosmin (740 MBq) and underwent planar and SPECT imagings 10 min after the injection. $^{201}$Tl (222 MBq) was injected and planar and SPECT imagings were performed 10 min after the injection. A large field of view dual detector gamma camera and computer system (GCA7200A, Toshiba) equipped with low-energy, high resolution, parallel hole collimators were used. Anterior and posterior simultaneous planar images (512 × 512 matrix, 1500 k counts) were acquired. The energy discriminator was centered on 71 keV for $^{201}$Tl and 140 keV photopeak for $^{99m}$Tc with a 20% window. Subsequently single photon emission computed tomography (SPECT)

Fig. 3  Thoracic coronal SPECT images of $^{201}$Tl show the accumulation of tracer in the tumor (arrow).

Fig. 4  Thoracic coronal SPECT images of $^{99m}$Tc-MIBI show tumor uptake of tracer in the tumor (arrow).

Fig. 5  A 66-year-old man with a malignant thymoma. Thoracic CT revealed a large anterior mediastinal tumor (arrow).

Fig. 6  Thoracic CT revealed an anterior mediastinal tumor and involvement of adjacent mediastinal structures (aorta), pleural disseminations and rib invasions.

data were acquired. The dual detector gamma camera rotated through 180° in a circular orbit in 60 steps of 50 sec each for $^{201}$Tl and $^{99m}$Tc SPECT. Butterworth and Shepp & Logan filters were used to reconstruct tomographic images. The parameter of Butterworth filter was order 8, and the cut-off frequency was 0.15 cycles/pixel for both tracers. As seen in Figures 2, 3 and 4, thoracic coronal SPECT images of $^{99m}$Tc-tetrofosmin, $^{201}$Tl and $^{99m}$Tc-
MIBI show the accumulation of each tracer in the tumorous lesion corresponding to the anterior mediastinal tumor on X-ray CT. The tumor-to-background ratios of planar and SPECT imagings were 1.60 and 1.98 for $^{99m}$Tc-tetrofosmin, 1.12 and 2.09 for $^{201}$Tl, and 1.19 and 1.80 for $^{99m}$Tc-MIBI, respectively.

Case 2
A sixty-six-year-old man came to our hospital because abnormal pleural thickening was pointed out in a routine chest X-ray. Thoracic CT revealed an anterior mediastinal tumor (Fig. 5) and involvement of the sternum, subcutaneous fat tissue and adjacent mediastinal structures (aorta), pleural dissections and rib invasions (Fig. 6). The result of CT guided biopsy indicated an invasive thymoma. We obtained informed consent from the patient. $^{99m}$Tc-tetrofosmin, $^{201}$Tl and $^{99m}$Tc-MIBI imagings were performed. The patient was injected with $^{99m}$Tc-tetrofosmin (740 MBq) and underwent planar and SPECT imagings 10 min and 3 hours after the injection. $^{201}$Tl (222 MBq) and $^{99m}$Tc-MIBI (740 MBq) were injected for the patient. Planar and SPECT imagings were obtained 10 min after the administration of both tracers. A $^{99m}$Tc-tetrofosmin thoracic anterior planar image showed increased tracer uptake in the primary mediastinal tumor and right humeral bone metastasis (Fig. 7A). A posterior thoracic planar image showed ribs and thoracic vertebral bone metastases and direct rib invasions from pleural dissections of malignant thymoma (Fig. 7B). Thoracic coronal SPECT (Fig. 8A) and transaxial SPECT (Fig. 8B) images of $^{99m}$Tc-tetrofosmin clearly showed intense tracer activity in primary anterior mediastinal tumor, direct sternum and subcutaneous fat tissue invasions and involvement of adjacent mediastinal structures (aorta, superior vena cava, mediastinum and pericardium), pleural dissections and bone metastases in the rt humeral bone, ribs and thoracic vertebrae. Thoracic coronal SPECT (Fig. 9A) and transaxial SPECT (Fig. 9B) images of $^{201}$Tl show tracer uptake in the primary tumor, direct sternum and subcutaneous fat tissue invasions and adjacent mediastinal invasions (aorta, superior vena cava and pericardium), pleural dissections and bone metastases (rt humeral bone, ribs and thoracic vertebrae). The tumor-to-background ratios of planar and SPECT imagings were 2.31 and 2.78 for $^{99m}$Tc-tetrofosmin, and 2.45 and 3.58 for $^{201}$Tl, respectively. In $^{99m}$Tc-tetrofosmin scintigraphy we acquired delayed images, and tumor-to-background ratios of planar and SPECT delayed images were 1.20 and 1.86, the retention ratios were −1.11.
and -0.92, and retention indices were -48.1 and -33.1, respectively. The retention ratio was obtained as follows: Delayed ratio = Early ratio. The retention index was obtained by means of the following equation: Delayed ratio = Early ratio/Early ratio × 100.

DISCUSSION

201TI uptake of various tumors has been reported including malignant and benign thymic tumor.13,14 The tumor seeking properties of 99mTc-MIBI are also well known.15-17 99mTc-tetrofosmin has recently been used as a new myocardial perfusion imaging agent, and has also shown potential utility as a tumor imaging agent for such conditions as parathyroid adenoma,1 breast cancer,2-4 lung cancer,5-8 thyroid cancer9,10 and other tumors.11,12 Although 99mTc-tetrofosmin uptake in mediastinal tumor was reported,13 there is no report on 99mTc-tetrofosmin uptake in bone and distant metastases from malignant thymoma.

There are several physical limitations to 201TI. The energy emitted is lower, the half-life is longer and the radiation dose to the patient is relatively higher. Compared with 201TI, 99mTc has some advantages over 201TI such as higher emitted energy, shorter half-life, smaller radiation dose, larger injected dose and better image quality.

As for the tumor-to-background (normal lung) ratio, in the planar images of case 1, the tumor-to-background ratio of the 99mTc-tetrofosmin (1.60) and 99mTc-MIBI (1.19) was superior to that of 201TI (1.12). But the tumor-to-background ratio of the SPECT images, 99mTc-tetrofosmin (1.98) and 99mTc-MIBI (1.80) was inferior to that of 201TI (2.09). In the planar images of case 2, the tumor-to-background ratio of the 99mTc-tetrofosmin (2.31) was inferior to that of 201TI (2.45) and in the SPECT images the tumor-to-background ratio of the 99mTc-tetrofosmin (2.78) was also inferior to that of 201TI (3.58). The 201TI tumor-to-background ratio was greater than that of 99mTc-tetrofosmin. This might be due to 99mTc-tetrofosmin showing higher uptake than 201TI in the normal lung. The 99mTc-tetrofosmin tumor-to-background ratio was greater than that of 99mTc-MIBI, and this might be due to 99mTc-tetrofosmin being cleared faster than 99mTc-MIBI18 from both the lungs and liver. Despite the better physical properties and imaging quality of 99mTc, it is disappointing that 99mTc-tetrofosmin did not always outperform 201TI in the tumor-to-background ratio. But 99mTc-tetrofosmin was judged to be comparable to 201TI on visual estimation and almost comparable to 201TI as to its tumor-to-background ratio also.

The early tumor-to-background ratios calculated from 99mTc-tetrofosmin planar and SPECT imagings were higher than the delayed ratios, suggesting that the early imaging with 99mTc-tetrofosmin might be the better choice for detecting malignant thymoma.

201TI is a K+ analogue. The uptake of 201TI by cells is related to cell membrane potential and Na+, K+ ATPase activity and might involve other K+ channels.20,21 201TI remains in the cytosolic compartment,21 whereas 99mTc-MIBI is localized mostly inside mitochondria due to negative mitochondrial membrane potential.22,23 99mTc-tetrofosmin is a monovalent lipophilic cation that rapidly enters the myocardial cells due to its lipophilic properties.24,25 The uptake of both 99mTc-tetrofosmin and 99mTc-MIBI is related to the Na+, K+ pump, and Na+/K+ antiport systems.26

The mechanism of uptake of 99mTc-MIBI and 99mTc-tetrofosmin into malignant cells and its exact localization
are not yet clear. The uptake of both tracers is known to depend on regional blood flow and on the mitochondrial content,22 because 99mTc-MIBI and 99mTc-tetrofosmin in vitro studies,28 appear to indicate that there is a connection with the multidrug resistance of P-glycoprotein, the 170-kDa protein coded by MDR1 (mammalian multidrug resistance gene). In addition, it was reported that accumulation of 99mTc-tetrofosmin in breast tumor cells in vitro is related to a P-glycoprotein similar to 99mTc-MIBI.28

The chemosensitivity of a tumor is important for its management. Increased expression of transmembranous p-glycoprotein, the product of multidrug resistance 1 gene, has resulted in multidrug resistance. The multidrug resistance p-glycoprotein system functions as an energy dependent efflux pump which reduces the amount of intracellular transporting cytotoxic agents, MIBI and tetrofosmin, in tumor cells. The accumulations of 99mTc-MIBI and 99mTc-tetrofosmin are inversely proportional to the level of p-glycoprotein expression.29-31 Therefore the accumulation of 99mTc-tetrofosmin in tumors provides us not only with the localization of the primary tumor and metastatic lesions but also the chemosensitivity of the tumor, which may predict the response to chemotherapy and selection of therapy management.

In conclusion, 99mTc-tetrofosmin imaging would be helpful in detecting both the primary tumor and metastatic lesions from malignant thymoma. Further investigations and larger clinical trials are needed to justify the potential usefulness of this tracer as a tumor detecting imaging agent.
