Diaphyseal medullary stenosis (DMS) is an extremely rare hereditary bone dysplasia, which was first described by Arnold in 1973. DMS has a high incidence of pleomorphic malignant fibrous histiocytoma (MFH). In this paper, we report the imaging findings of DMS with pleomorphic MFH of the bone, mainly describing $^{99m}$Tc hydroxymethylenediphosphonate (HMDP) and thallium-201 ($^{201}$Tl) chloride scintigraphy findings. On $^{99m}$Tc HMDP scintigraphy, focal increased uptake area of the right femur corresponded to the area of bone marrow invasion of the tumor and bone infarction. The mechanism of the uptake of $^{99m}$Tc HMDP to the extraosseous lesion was not clear. On $^{201}$Tl chloride scintigraphy, the increased uptake of the periphery of the mass seemed to reflect the aggressiveness of invasion and the cellularity.

Key words: diaphyseal medullary stenosis, malignant fibrous histiocytoma, $^{99m}$Tc HMDP, $^{201}$Tl chloride
