muscle, liver, kidney, spleen and bone were measured by a well-type scintillation counter, and the retention value in each tissue was calculated and expressed as a percent dose per gram-tissue weight. In order to determine the biological half time of $^{113}$Sn-citrate in rats, the rats to which $^{113}$Sn-citrate were injected intravenously were measured by the animal whole body counter for sixteen days.

The retention values of $^{113}$Sn-citrate in bone were 2.0%/g at 1 hour, 1.9%/g at 3 hours and 2.0%/g at 24 hours. And bone-muscle concentration ratios were 77 at 1 hour, 212 at 3 hours and 389 at 24 hours, bone-blood concentration ratios were 24 at 1 hour, 110 at 3 hours and 715 at 24 hours, bone-liver concentration ratios were 31 at 1 hour, 33 at 3 hours, 46 at 24 hours. In bone-organs concentration ratios, $^{113}$Sn was superior to $^{85}$Sr at 1 hour, but $^{113}$Sn was inferior to $^{85}$Sr at 24 hours after injection. Retention curve of $^{113}$Sn-citrate in rats showed rapid phase and slow phase and half time of rapid phase was 18 minutes and half time of slow phase was 30 days.

As a suitable nuclide for clinical bone scanning, the production of $^{117m}$Sn by atomic reactor is being under investigation.

**On Preparation of $^{99m}$Tc-Sulfur Colloid for Improved Bone Marrow Imaging**

Department of Radiology, Research Institute for Tuberculosis & Cancer, Tohoku University, Sendai

$^{99m}$Tc$_2$S$_7$ colloids (Tc-C) have been accepted as one of the best available RE imaging agents, especially that of liver. Critical reviews clarify most of their preparations are not necessarily appropriate enough for marrow delineation. Especially in dynamic assessment of marrow RE function, uniform colloidal particles of relatively smaller size are mandatory. Our efforts on development of Tc-C just suitable for this purpose was reported here.

Various modifications of the two major methods of sulfurization with Na$_2$S$_2$O$_3$ and H$_2$S gas were compared in respect to blood clearance T-1/2 of of radiocolloids, organ distribution, assay for free $^{99m}$TcO$_4^-$ by paper chromatography, and clinical and experimental marrow scintigraphy.

Na$_2$S$_2$O$_7$ method: Hepatic uptake of Tc-C ranged between 70 and 85% given dose, that of spleen between 0.3 and 3.8 respectively, and marrow uptake was assumably between 6.6 and 10%.

H$_2$S gas method: The longest reaction time of 50 min resulted in a greater uptake by liver and lungs, and less marrow deposition when volume ratio of gas to $^{99m}$TcCO$_4^-$ was kept constant at 4:1. Tc-C from 1:1 of gas volume ratio revealed higher blood retention. Its distribution pattern, however, was not significantly different from those of 2:1 and 4:1. Satisfactory marrow scintigrams were obtained of rabbits and patients alike with Tc-C prepared with the H$_2$S gas volume ratio to $^{99m}$TcCO$_4^-$ of 2:1 or greater, and the reaction time of 20 min or longer.

In interpreting marrow scintigrams, it should be taken into account that marrow RE uptake of radiocolloids may greatly be affected by different colloidal preparations.
